PRACTICE QUESTIONS - 04

NUMPY QUESTIONS

1. Create a 4X2 integer array and print its attributes.
2. Create a 5X2 integer array from a range between 100 to 200 such that the difference between each element is 10.
3. Following is the provided numPy array. Return the array of items in the third column from all rows.
 - Sample array: `SampleArray = np.array([[11, 22, 33], [44, 55, 66], [77, 88, 99]])`
4. Split the following array into 4 equal-sized sub-arrays:
 - `sampleArray = np.array([[34, 43, 73], [82, 22, 12], [53, 94, 66]])`
5. Print the shape of a 2-D array after converting it from a 1D array of 10 elements.
6. Create a 2D array of shape 7x5 with numbers 1 to 35, then:
 - Slice elements from the second row to the sixth row.
 - Slice elements from the third to fifth columns.
 - Extract specific elements (e.g., row indices [0, 2, 4] and column indices [1, 3]).
7. Reverse rows and columns of a 2D array.
8. Find and print all values greater than 10 in a given array:
9. Replace all odd numbers in a NumPy array with -1.
10. Create a structured array representing a Point with x and y coordinates, then assign values to it.
